NOISE POLLUTION

Patrick Barry*

INTRODUCTION

The authors of Noise: A Flaw in Human Judgment are a trio of intellectual heavy hitters: Nobel Prize-winner Daniel Kahneman, constitutional law scholar Cass Sunstein, and former McKinsey consultant (and current management professor) Olivier Sibony. As prolific as they are prominent, the three of them have collectively produced over fifty books and hundreds of articles, including some of the most cited research in social science. If academic publishing ever becomes an Olympic sport, they’ll be prime medal contenders, particularly if they get to compete as a team or on a relay. Their combined coverage of law, economics, psychology, medicine, education, finance, political science, corporate strategy, statistics, and even Star Wars gives the book the feel of a cognitive decathlon.

At the center of it all is a key distinction: the difference between bias and noise.

He is also a visiting lecturer at the University of Chicago Law School. He wishes to thank Tamar Alexanian, Jonathan Concepcion, Saket Kulkarni, Abby Schmidt, and Daniella Therese Abrenica for their excellent, noise-free edits and research assistance. Daniella deserves special recognition for creating the images of dart board on pages 2 + 3.

2 For a sense of the authors’ cumulative range, see, e.g., DANIEL KAHNEMAN, THINKING, FAST AND SLOW (2011); BERNARD GARRETTE, COREY PHELPS, AND OLIVER SIBONY, CRACKED IT! HOW TO SOLVE BIG PROBLEMS AND SELL SOLUTIONS LIKE TOP STRATEGY CONSULTANTS (2018); OLIVIER SIBONY, YOU’RE ABOUT TO MAKE A TERRIBLE MISTAKE! I. BIAS, NOISE, AND DART BOARDS

Judgments are biased, the authors explain, when they are “systematically off target.” But judgments are noisy when “people who are expected to agree end up at very different points around the target.” To help illustrate this contrast, the authors begin the book with an example that involves a bullseye at a shooting range. When I summarize the main points of the example for my law students, however, I switch the visual to a bullseye on a dart board and ask them to imagine that a group of people throw a bunch of darts at it. Each person aims directly for the bullseye. Each person tries their best. Yet when we take a look at where their darts end up, we notice that every single one of them lands slightly to the right of the bullseye. Not to the left. Not above. Not below. All cluster in the same spot to the right.

That’s what bias is, according to Kahneman, Sibony, and Sunstein. The darts are “systematically off target.”

Think here of the many studies that have uncovered racial bias and gender bias in the way hiring decisions are made, criminal sentences are delivered, and mortgage rates are offered. There is a (depressingly) recognizable pattern to these forms of discrimination. We can predict how the next decision in the queue is going to go.

Or, to take a less grave example, consider a research paper by the economist Noland Kopkin called “The Nature of Regional Bias in Heisman Voting.” Using a data set that stretched over twenty-five years, Kopkin found that the hundreds of journalists and other pundits who vote every year

for college football’s most prestigious award, the Heisman Trophy, have exhibited a consistent bias towards players from their own region. Voters from the Northeast favor players from the Northeast. Voters from the Southwest favor players from the Southwest. And so on.

The bias isn’t egregious, and Kopkin suggests that the overall effect is decreasing now that there are more and more ways to watch games from every region. But if we imagine each of those votes as darts on the dart board we’ve been talking about, we’d probably see quite a bit of clustering. There’d be a cluster around the Northeast of the dartboard, representing the bias of voters from that region. There’d be a cluster around the Southwest of the dartboard, representing the bias of the voters from that region. There’d be clusters all over the place.

Not so with noise. When the problem is noise, there aren’t any clusters. There aren’t predictable patterns. There’s simply a random assortment of darts.

10 Each of the six regions—Northeast, Mid-Atlantic, South, Southwest, Midwest, and Far West—are given 145 votes. All living Heisman Trophy winners are also allowed to vote, and one collective vote is awarded based on a fan poll. II. NOISY JUDGMENTS, MAJOR DAMAGE

Bias and noise are both big problems. But Kahaneman, Sibiony, and Sunstein worry that concerns about bias, however legitimate, have overshadowed concerns about noise. “The topic of bias has been discussed in thousands of scientific articles and dozens of popular books,” they write, “few of which even mention the issue of noise.”12 Bias has become “the star of the show,” while noise is treated as “a bit player, usually offstage.”13 Their book tries to correct that imbalance, a task they believe is particularly important given the stakes involved. Here are few of the areas they identify where noisy judgments can cause major damage:

- **Doctor Diagnoses**: “Faced with the same patient, different doctors make different judgments about whether patients have skin cancer, breast cancer, heart disease, tuberculosis, pneumonia, depression, and a host of other conditions.”14

- **Child Custody Decisions**: “Case managers in child protection agencies must assess whether children are at risk of abuse and, if so, whether to place them in foster care. The system is noisy, given that some managers are much more likely than others to send a child to foster care.”15

- **Patent Applications**: “The authors of a leading study on patent applications emphasize the noise involved: ‘Whether the patent office grants or rejects a patent is significantly related to the happenstance of which examiner is assigned the application.’”16

III. PERSONALITY CHANGE

One source of these distortions is what the authors call *occasion noise*: when faced with the same decision at different times, people make conflicting judgments. Asked to review an identical set of X-rays several months apart, for example, a set of doctors disagreed with their original judgment between 63% and 92% of the time.17 That’s not doctors coming to a different

conclusion than other doctors. That’s doctors coming to a different conclusion than themselves.

Or consider a frequent criticism of personality tests like the Meyer-Briggs Type Indicator. If you take the test more than once, there’s a good chance you’ll find out that your “personality” has changed.\(^\text{18}\)

That happened to Adam Grant, an organizational psychologist at the University of Pennsylvania and author of bestselling books such as *Give and Take* and *Think Again*. In an article titled “Goodbye to the Meyer-Briggs Typical Indicator, the Fad That Won’t Die,” Grant shares the incompatible scores he received.\(^\text{19}\) The initial time he took the test he was classified as an “INTJ,” meaning he was allegedly more introverted than extroverted, more intuiting than sensing, more thinking than feeling, and more judging than perceiving. These labels initially seemed to match his own image of himself. “Although I spend much of my time teaching and speaking on stage, I am more of an introvert—I’ve always preferred a good book to a wild party. And I have occasionally kept lists of my to-do lists.”\(^\text{20}\)

Yet when Grant took the same test a few months later, each of those classifications reversed. Now, apparently, he was a big-time extrovert. “Suddenly, I had become the life of the party, the guy who follows his heart and throws caution to the wind.”\(^\text{21}\)

Grant’s experience is a textbook example of occasion noise and also one of the reasons he says that “when it comes to accuracy, if you put a horoscope on one end and a heart monitor on the other, the Meyers-Briggs Test falls about halfway in between.”\(^\text{22}\) In other words, the test has a lot of noise and not much use.

### IV. (UNDER) PERFORMANCE

The authors of *Noise* don’t mention Grant’s essay. But he is one of many academic luminaries who provides a cover blurb for the book. “Get ready,”

he raves, “for some of the world’s greatest minds to help you rethink how you evaluate people, make decisions, and solve problems.”

He has also done an extensive research project as a consultant for Facebook to help fix something the *Noise* authors devote an entire chapter to: employee performance reviews.

One complaint about performance reviews—especially those that happen only once a year—is the time lag involved. The reviews come long after the person being reviewed could have used the instruction and guidance the process is designed to provide. Here’s how a manager at PricewaterCoopers, which is one of the many major companies that have moved away from annual performance reviews, expressed that frustration. “You don’t give elite athletes coaching at the end of the season. You give it in the middle of the game.”

The authors of *Noise*, however, focus on a different problem. Discrepancies in evaluations often have more to do with who is doing the evaluating than with the employees themselves. Imagine, for example, that you ran a race and three different stopwatches evaluated how well you did compared to the other runners. One stopwatch said you finished second overall. Another said you finished eleventh. And the third didn’t even put you in the top fifty.

Wouldn’t that be kind of frustrating? Wouldn’t you think something was wrong with the way your performance in the race was assessed?

Any student who has picked a class based on whether the teacher is a hard or easy grader has faced a similar issue. For over a century, research has shown that teachers vary widely on how they evaluate students. In one of the most cited experiments, the same two English papers were given to 200

27 For an overview of this research, including a discussion of a few studies that push back on the research that shows high grade variability, see Susan M. Brookhart et al., *A Century of Grading Research: Meaning and Value in the Most Common Educational Measure*, 86 Rev. Educ. Rsch. 803, 806-20 (2016).
teachers. The authors of the study—Daniel Starch and Edward Elliott of the University of Wisconsin—were quite disturbed by the huge discrepancy in the grades the papers received. One paper, for example, earned a near perfect score from some teachers, but it received a failing score from others. “It is almost shocking to a mind of more than ordinary exactness,” Starch and Elliot said of the overall results, “to find that the range of marks given by different teachers to the same paper may be as large as 35 or 40 points.”

When Starch and Elliot tried the same experiment with math teachers—a group presumably more committed to objective, stable standards—the variation persisted. Identical student responses to questions about theorems, bisecting angles, and the hypotenuse of a triangle. Yet widely different grades. That’s not bias. (There was no identifying information about the students’ race, gender, or other characteristics which could have improperly influenced the teachers.) That, alarmingly, is noise.

V. DECISION HYGIENE

By the end of the book, it is hard not to think that we live in an exceedingly noisy world. There is noise in the way actuaries calculate insurance premiums. There is no noise in the way judges decide asylum cases. There is noise virtually everywhere, including in high-stakes judgments made every day in banks, start-ups, daycares, law firms, nonprofits, and the C-suites of Fortune 500 companies. It’s enough to make you want to invest in a really good pair of earplugs.

A better approach, however, would be to follow the steps the authors suggest lead to good “decision hygiene.” Here are a few that one of those authors, Olivier Sibony, highlighted in an interview soon after the book was published.

32 Id. 6-7.
33 Id. 226
• **Aggregate multiple independent judgments:** “Whenever you have different people making judgments, rather than assign the judgment to one person or gathering three people to talk about it around the table, get them to make their judgments independently and take the average of that.”

• **Invest in competence:** “Some people are going to be better than others at any judgment. In medicine, for instance, some diagnosticians are better than others. If you can pick the better people, that helps. The better people are going to be more accurate; they are going to be less biased but they’re also going to be less noisy. There is going to be less random error in their judgments.”

• **Use relative rather than absolute scales:** “If you replace an absolute scale with a relative scale, you can eliminate a very big chunk of the noise. Think of performance evaluations again. Saying that someone is a ‘two’ or a ‘four’ on a performance-rating grid—even when you have the definition of what those ratings mean—remains fairly subjective, because what ‘an outstanding performer’ or ‘a great relationship skill’ means to you is not necessarily the same thing that it means to me. But if you ask, ‘Are Julia’s relationship skills better than those of Claudia?’ that’s a question I can answer if I know both Julia and Claudia. And my answers are probably going to be very similar to yours. Relative judgments tend to be less noisy than absolute ones.”

Implementing these ideas is unlikely to win you any awards for innovative management. Nor will conducting the “Noise Audit” the authors attach as an appendix to the book.35 As Sibony acknowledges, noise prevention is “a little bit thankless.”36

But what you miss out in terms of gratitude and acclaim, you might gain in terms of efficiency, accuracy, and fairness. You don’t need Daniel Kahneman’s Nobel Prize in Economics to know that’s a pretty good trade-off.
